Linear mixed models in R Day 2

JONAS WALTHER

RT ~ Context + (1 | Subject)

Independent variables/fixed effects

Random effects

Dependent variable

RT ~ Group * Context + Age + (1 + Context | Subject) + (1 | Item)

Dependent variable

Independent variables/fixed effects

Random effects (crossed between Subject and Item)

RT ~ Group * Context + Age + (1 + Context | Subject) + (1 | Item)

Independent variables/fixed effects

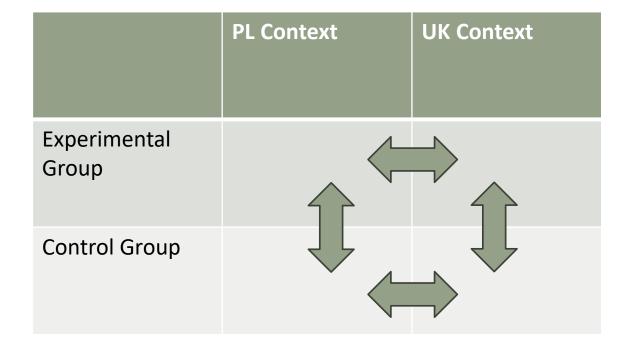

: - interaction

* - short-form for single fixed effects and interaction between effects; equals:

Group + Context + Group:Context

Interactions

Group*Context = Group + Context + Group:Context

Interactions

No interaction – effects are additive

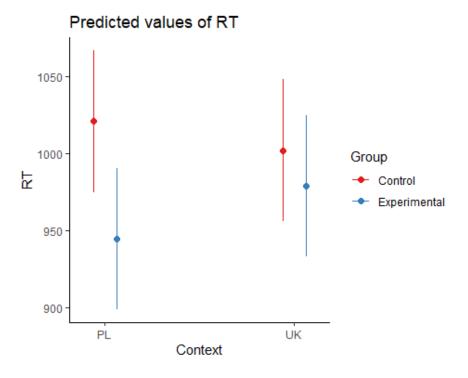

Sign. Interaction – effects are not additive

	PL Context	UK Context		PL Context	UK Context
Experimental Group	500ms	550ms	Experimental Group	500ms	550ms
Control Group	480ms	530ms	Control Group	480ms	480ms

Interactions

Significant interactions do not give sensible information on their own

Additional tests are necessary to understand their effects

RT ~ Group * Context + Age + (1 + Context | Subject) + (1 | Item)

Dependent variable

Independent variables/fixed effects

Random effects (crossed between Subject and Item)

: - interaction

* - short-form for single fixed effects and interaction between effects; equals:

Group + Context + Group:Context

Crossed vs. nested random effects

<u>Crossed</u>: each level of one random effect occurs at each level of the other random effect, and vice versa

• e.g., each subject sees every item, and each item is seen by every subject

<u>Nested</u>: There are some levels of one random effect (the nested one) that only occur within one level of the other random effect (the nesting one)

 E.g. tested several students in several schools. A given student only occurs in one school, not in every school

A model can include both (e.g. Students nested under Schools, but Items fully crossed with those)

```
RT ~ Group * Context + Age + (1 + Context | Subject) + (1 | Item)
```

Nested random effect:

```
RT ~ Group * Context + Age + (1 | School/Student)
```

Identical to:

```
RT ~ Group * Context + Age + (1 | School) + (1 | School:Student)
```

Summary-Output of an LME

Amount of variance for each random term

Coefficients for fixed effects

Correlation of fixed effects (NOT correlation of - predictors, collinearity)

```

Random effects-Output

For each random effect, how much each subject's effect differs from the overall fixed effect

RT ~ Group * Context + Age + (1 + Context | Subject) + (1 | Item)

Dependent variable

Independent variables/fixed effects

Random effects (crossed between Subject and Item)

- Random effects are grouping factors
- Always categorical
- Recommended to have at least five levels

Syntax of random effects

(1 + Context | Subject)

Random intercept

Random slopes

Variable name for coding levels of random factor

We added subject intercepts

$$y_{iCond} = \beta_0 + \beta_{Cond} x_{iCond} + \epsilon_{Cond} + u_{0i}$$

But we can also add subject slopes

$$y_{iCond} = \beta_0 + (\beta_{Cond} + u_{1i})x_{iCond} + \epsilon_{Cond} + u_{0i}$$

 eta_0 -average naming latency

 u_{0i} -subject dependant adjustment

 ϵ_{Cond} -error/noise term

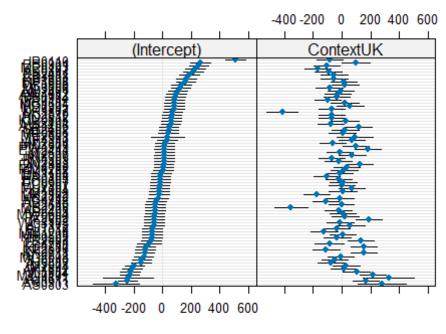

Subject adjustments for intercept and fixed effects

RT ~ Group + Context + Group:Context + Age + AoA + Trial + (1 + Context | Subject) + (1 + Context | ItemNr)

```
library(lattice)
print(dotplot(ranef(model GeneralModel, condVar = TRUE)))
```

Subject

Syntax of random effects

(1 + Context | Subject)

Random intercept

Random slopes Variable name for coding levels of random factor

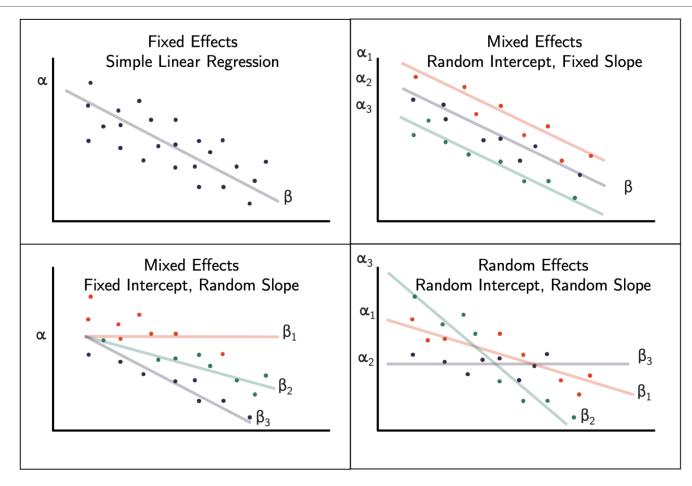

- random intercept and random slope are correlated with each other
- | | no correlations between random effects

(Context | Subject)

This expands to:

(0 + Context | Subject) + (1|Subject)

Random intercept and random slope

Random intercept and no slope

```

Assumptions of linear mixed models

The explanatory variables are related linearly to the response and additive.

The residuals have constant variance.

The residuals are normally distributed.

The explanatory variables are related linearly to the response.

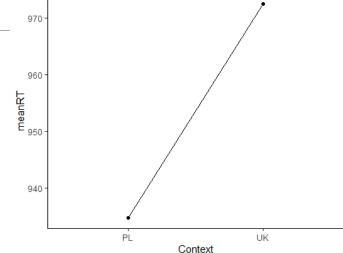

Linear mixed effects models rely on linear relationships between the variables

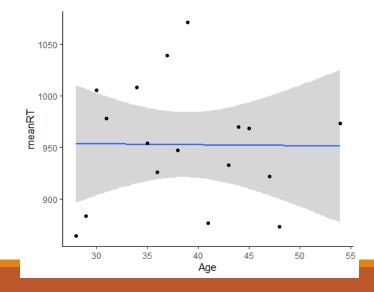

Categorical variables are treated as 2-level variables

Continuous variables are used in linear regression

But many effects are non-linear:

- Introduction of additional predictors and constructs to approximate non-linear effects
- Switch to Generalised-Mixed-Models and other tools

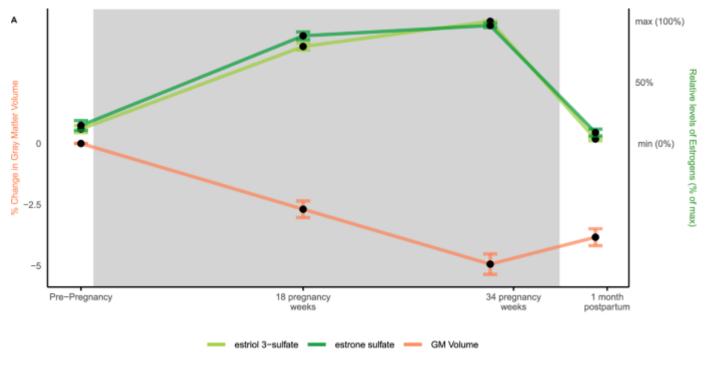

Fixed effects in LMEs are always treated as linear

Many processes are non-linear

LMEs allow the abstraction of non-linear effects as linear ones

-> but you lose information and you could introduce erroneus effects

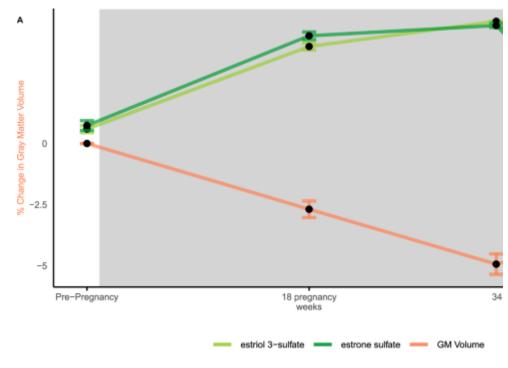

Servin-Barthet et al. (2025)

Fixed effects in LMEs are always treated as linear

Many processes are non-linear

LMEs allow the abstraction of non-linear effects as linear ones

-> but you lose information and you could introduce erroneus effects

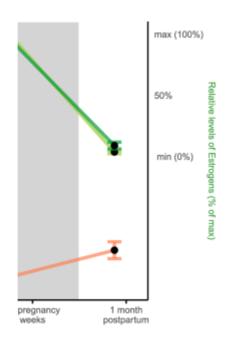

Servin-Barthet et al. (2025)

Fixed effects in LMEs are always treated as linear

Many processes are non-linear

-> but you lose information and you could introduce erroneus effects

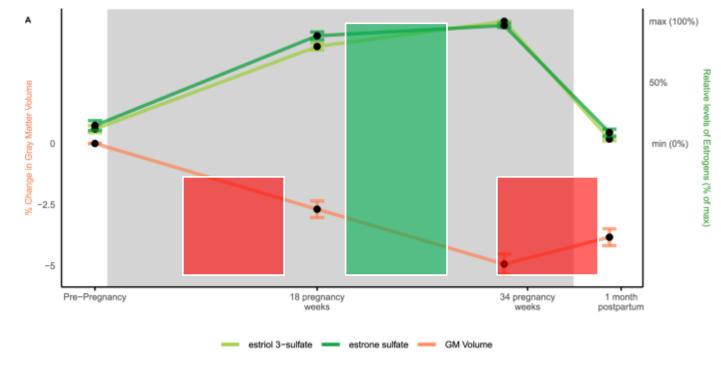

Fixed effects in LMEs are always treated as linear

Many processes are non-linear

LMEs allow the abstraction of non-linear effects as linear ones

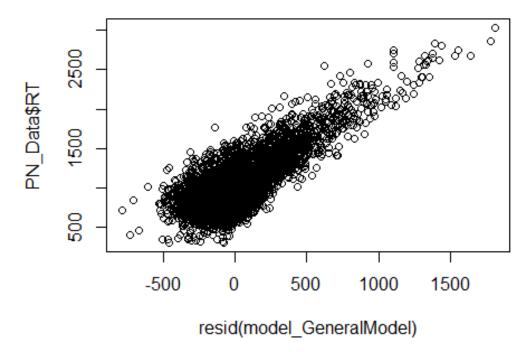

-> but you lose information and you could introduce erroneus effects

Servin-Barthet et al. (2025)

The explanatory variables are related linearly to the response.

plot(resid(model GeneralModel), PN Data\$RT)

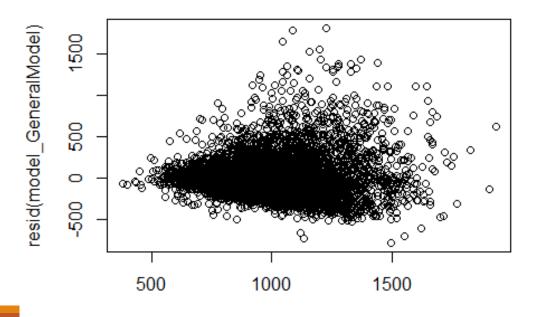

The residuals have constant variance.

$$y_{iCond} = \beta_0 + \beta_{Cond} x_{iCond} + \epsilon_{Cond} + u_{0i}$$

Plotting residuals against fitted values will indicate if there is non-constant error variance.

plot(fitted(model_GeneralModel), resid(model_GeneralModel))

fitted(model GeneralModel)

Homoscedasticity

We are looking for a consistent vertical spread

-> variability should stay the same across different levels of the dependent variable

The errors are Normally distributed.

The errors are Normally distributed.

```
res_model <-
residuals(model_GeneralModel)
qqnorm(res_model)</pre>
```

If the line curves away from the diagonal, the normality assumption is not met.

The solution might be transformation of the data.

Normal Q-Q Plot 1500 Sample Quantiles 500 0 500 Theoretical Quantiles

Transforming data

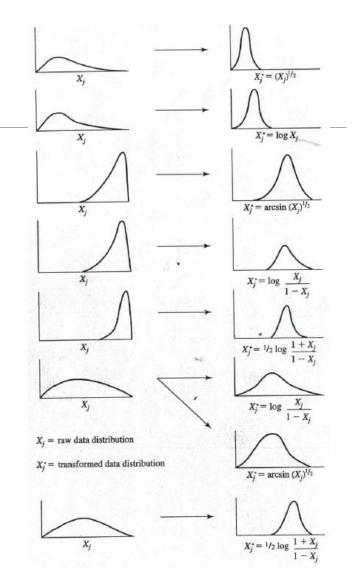

Many experimental results are not normally distributed (RT, questionnaire scales etc.)

Box-Cox procedure can be used to determine best transformation

However, transformation can also lead to bad results and a switch to GLM might be better (Lo and Andrews, 2015)

Transforming data

Data transformation is done by applying some function to the data, which changes the distribution shape, but maintains the overall data distribution

https://www.statisticssolutions.com/transforming-data-for-normality/

Box-Cox package

Box-Cox Transformation

 \circ Find the exponent λ to approximate the normal distribution as close as possible

Not easily implemented for LMEs

But in linear regression

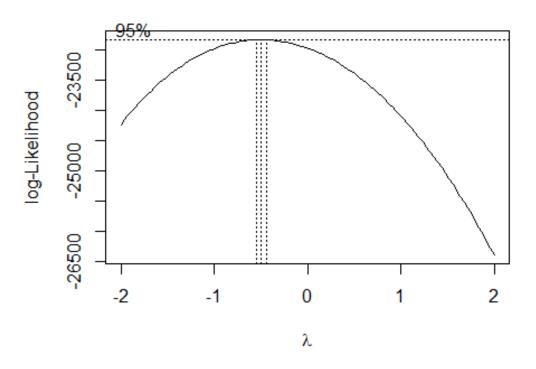

Lambda value (λ)	Transformed data (Y')
-3	Y^-3 = 1/Y3
-2	Y^-2 = 1/Y2
-1	Y^-1 = 1/Y1
-0.5	$Y^-0.5 = 1/(V(Y))$
0	log(Y)
0.5	$Y^0.5 = V(Y)$
1	Y^1 = Y
2	Y^2
3	γ^3

How to use Box-Cox package

```
library(MASS)

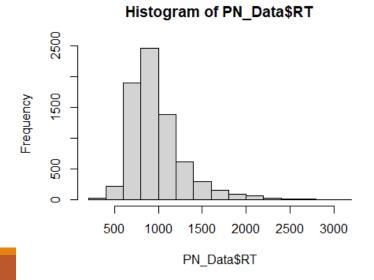

m0 <- lm(RT~1+Context*Group, data
= PN_Data)

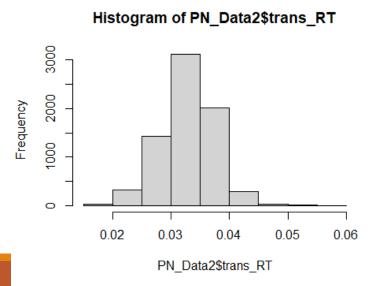

boxcox(m0)</pre>
```

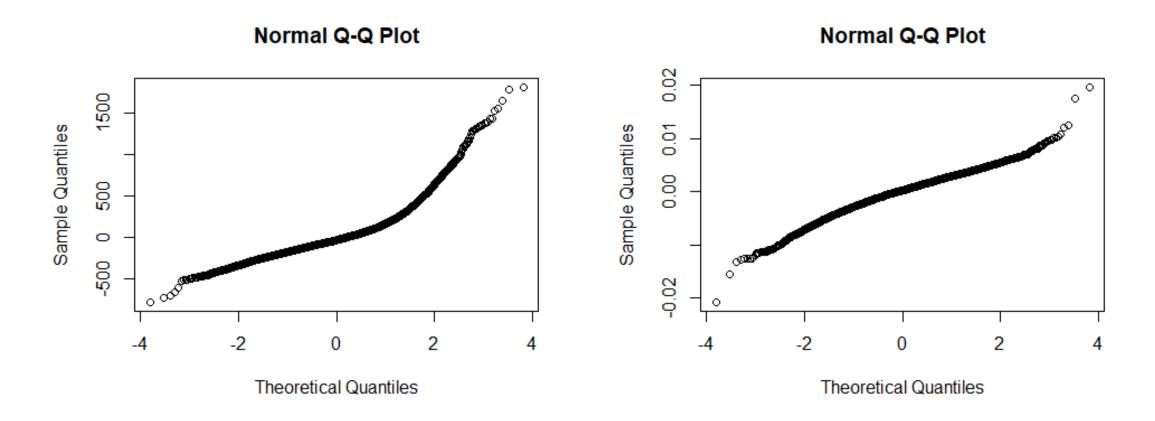

Transforming reaction times

```
hist(PN_Data$RT)
PN_Data2 <-
    PN_Data %>%
    mutate(trans_RT = 1/sqrt(RT))
hist(PN_Data2$trans_RT)
```

Re-Test: normal distribution of residuals

Multicollinearity

Predictors can be highly correlated and cause problems with the model

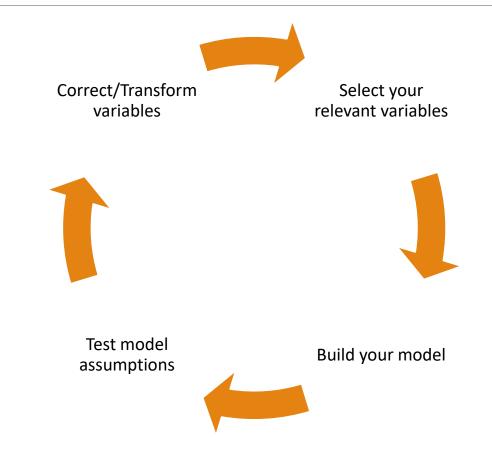

Tested with the Variance Inflation Factor (VIF)

```
library(car)
vif(model GeneralModel)
##
          Group
                    Context
                                                              Trial
                                     Age
                                                  AoA
##
       1.524975 1.981377
                                 1.274221
                                             1.199493
                                                           1.000071
## Group:Context
##
       2.218775
```

VIF of 1 indicates no correlation between variables

VIF of 5 or higher might be problematic and coefficient estimates of the model might be highly unreliable

Creating your own models

Example experiment

Bilingual speaker name pictures in a Polish and an English Context

Every speaker saw every picture in both contexts

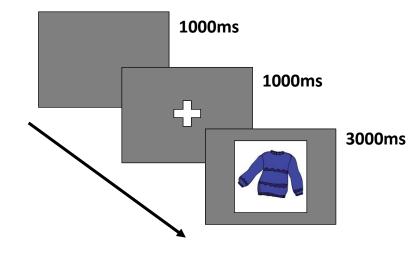

Experimental variables:

Context - UK vs PL

Group – Experimental vs Control

Grouping factors: Subject and Item

Dependent variable: naming latency
